Explanation: Why SSH should not be opened to `0.0.0.0/0`

Opening SSH (Port 22) to `0.0.0.0/0` means allowing inbound connections from **anywhere on the public internet**. This introduces major security risks:

1. **Brute-Force and Automated Bot Attacks:** As soon as an instance gets a public IP, automated bots and scripts constantly scan Port 22 across the internet. Opening it globally invites thousands of automated login and brute-force attempts daily.
2. **Credential Stuffing and Vulnerability Exploitation:** If an attacker manages to brute-force weak credentials or exploit a vulnerability in the SSH service, they gain full root/administrative access to your server.
3. **Violation of Least Privilege:** Security best practices dictate that administrative ports should only be exposed to trusted, known entities (such as your specific local IP address or a secure VPN), drastically reducing the attack surface.
